

# Smoke Detector

(wireless)

## What is a Smoke Detector?

On detection of smoke, the wireless smoke detector will raise two alarms. Firstly an alarm will sound to alert anyone present, and secondly the alarm will be raised to a response centre where an experienced operator will alert the emergency services. Because the process is automatic and immediate, the risks to life and property are reduced.

## How does it work?

By using wireless technology, there is minimal disruption to fixtures and fittings during the installation process and the smoke detectors can be easily relocated to another area if the need arises.

When activated, the smoke detector transmits an alarm call via the base unit to the response centre where the most appropriate and immediate action is taken.

## Why is it needed?

Fire poses a serious threat to vulnerable people at home. Every year fires in the home cause hundreds of deaths and damage many thousands of homes. Homes equipped with smoke detectors continue to discover fires more quickly than those without, and are associated with lower casualty rates and less damage. Installing wireless smoke detectors is a simple and straightforward method of providing a monitored fire detection system in the home.

## Who is it for?

The smoke detector is for anyone who is at risk in their home and requiring additional peace of mind.
